solving problems with LoRA

finetuning analysis of QWEN7B on NLI4CT:

baseline (no finetuning): 65.8% accuracy

finetuned: 74.4% accuracy

Experiment:

Test on the baseline and the finetuned model with a test dataset with a fixed premise (generalist one):

baseline : 50% accuracy (almost always predict contradiction), good thing because the premise is false so in fact, almost all the hypothesis are contradiction given this premise
on the finetuned model: 57.2% accuracy : in show that the models gives a true answer more than 50% of time. That's maybe because there are bias in the data and sometimes the model learns to detect if a statement is true or false, just by reading the statement and the way it is formulated.
